

Mass Relationships in Chemical Reactions

Chapter 3

Molar mass and the mole

- one mole is defined as the number of carbon atoms in exactly 12.000000 grams of pure ^{12}C .
- From the sugar example, a mole of $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ would have a mass of 342.299 grams.
- This quantity is known as the **molar mass**, a term that is often used in place of the terms *atomic mass* or *molecular mass*.

Determine the molar mass of NaOH?

NaOH contains one Na atom + one oxygen atom + one hydrogen atom

Molar mass = 1 x mass of Na atom + 1 x mass of O atom + 1 x mass of H atom

The masses of the elements can be obtained from the periodic table.

$$= 1 \times 22.99 + 1 \times 16.00 + 1 \times 1.008 = 39.99 \text{ g}$$

Molar mass of NaOH = 39.99 g

Calculate the molecular weight of the following:

a) H_2SO_4

$$\text{MW of } \text{H}_2\text{SO}_4 = 2 \times \text{H} + 1 \times \text{S} + 4 \times \text{O} = 2 \times 1 + 1 \times 32 + 4 \times 16 = 98 \text{ g/mole}$$

b) CH_3OH

$$\begin{aligned} \text{MW of } \text{CH}_3\text{OH} \\ = 4 \times \text{H} + 1 \times \text{C} + 1 \times \text{O} = 4 \times 1 + 1 \times 12 + 1 \times 16 = 32 \text{ g/mole} \end{aligned}$$

c) Lauric acid $\text{C}_{12}\text{H}_{24}\text{O}_2$

$$\text{MW of } \text{C}_{12}\text{H}_{24}\text{O}_2 = 24 \times \text{H} + 12 \times \text{C} + 2 \times \text{O} = 24 \times 1 + 12 \times 12 + 2 \times 16 = 200 \text{ g/mole}$$

3

Number of moles

- To determine the number of moles use the following formula or triangles:

$$\text{number of moles} = \frac{\text{mass (g)}}{\text{molar mass (g / mole)}}$$

How many moles are there in 22.99 g of sodium?

$$\text{number of moles} = \frac{\text{mass (g)}}{\text{molar mass (g / mole)}} = \frac{22.99 \text{ g}}{22.99 \text{ g / mole (from the periodic table)}}$$

number of moles = 1 mole.

How many moles are there in 1 g of chlorine?

$$\text{number of moles} = \frac{\text{mass (g)}}{\text{molar mass (g / mole)}} = \frac{1 \text{ g}}{35.45 \text{ g / mole (from the periodic table)}}$$

number of moles = 0.028 mole.

4

How many grams are there in 0.10 mole of CH₄?

First calculate the molar mass of CH₄

$$\begin{aligned}\text{Molar mass of CH}_4 &= 1 \times \text{mass of C atom} + 4 \times \text{mass of H atoms} \\ &= 1 \times 12.01 + 4 \times 1.008 = 16.02 \text{ g / mole}\end{aligned}$$

Then use the formula:

$$\begin{aligned}\text{mass of CH}_4 &= \text{number of moles} \times \text{molar mass of CH}_4 \\ &= 0.10 \text{ mole} \times 16.02 \text{ g/ mole} = 1.602 \text{ g}\end{aligned}$$

Which one is the lightest in mass: one mole of hydrogen, one mole of sodium, one mole of iron, one mole of sulfur?

One mole for an element contains the atomic mass of the element.

Atomic mass of H = 1.008 g / mole, Atomic mass of Na = 22.99 g / mole,

Atomic mass of Fe = 55.85 g / mole, Atomic mass of S = 32.07 g / mole.

The lightest one is one mole of hydrogen

The heaviest one mole is the iron.

5

• Avogadro's number and the mole

1 mole of anything contains the Avogadro's Number (N_A) of this thing

$$\text{Avogadro's Number (NA)} = 6.02214 \times 10^{23}$$

1 mole of particles = 6.02214 x 10²³ particles for any substance

1 mole of shoes = 6.02214 x 10²³ shoes

1 mole of cars = 6.02214 x 10²³ car

1 mole of carbon atoms = 6.02214 x 10²³ carbon atoms

1 mole of water molecules = 6.02214 x 10²³ water molecules

Number of particles = number of moles x Avogadro's number

6

To calculate the number of particles (atoms, molecules, shoes....etc) use the following formula:

$$\text{Number of particles} = \text{number of moles} \times \text{Avogadro's number}$$

Calculate the number of atoms in 2 mole of hydrogen?

Number of hydrogen atoms =

$$2 \text{ moles of H} \times 6.02214 \times 10^{23} \text{ H atom / mole}$$

$$\text{Number of hydrogen atoms} = 1.20 \times 10^{24} \text{ H atom}$$

Calculate the number of atoms in 6.46 grams of helium (He)?

$$\text{number of moles} = \frac{\text{mass (g)}}{\text{molar mass (g / mole)}} = \frac{6.46 \text{ g}}{4.003 \text{ g / mole (from the periodic table)}}$$

number of moles = 1.61 mole.

Number of He atoms = number of moles \times Avogadro's number

$$= 1.61 \text{ moles of He} \times 6.02214 \times 10^{23} \text{ He atom / mole}$$

$$= 9.66 \times 10^{23} \text{ He atom}$$

7

Caffeine is a stimulant drug and it is found in coffee, tea and beans. Its molecular formula is $\text{C}_8\text{H}_{10}\text{N}_4\text{O}_2$. Calculate the number of oxygen atoms in 19.40 grams of caffeine.

Molar mass of caffeine = $8 \times \text{C} + 10 \times \text{H} + 4 \times \text{N} + 2 \times \text{O}$

$$= 8 \times 12 + 10 \times 1 + 4 \times 14 + 2 \times 16 = 194 \text{ g / mole}$$

$$\text{number of moles} = \frac{\text{mass (g)}}{\text{molar mass (g / mole)}} = \frac{19.40 \text{ g}}{194 \text{ g / mole (from the periodic table)}}$$

number of moles = 0.10 mole

Total number of $\text{C}_8\text{H}_{10}\text{N}_4\text{O}_2$ molecules = number of moles $\times N_A$

$$= 0.10 \text{ moles} \times 6.022 \times 10^{23} \text{ molecules / mole}$$

$$\text{Total number of } \text{C}_8\text{H}_{10}\text{N}_4\text{O}_2 \text{ molecules} = 6.022 \times 10^{22} \text{ molecules}$$

$$\text{Number of oxygen atoms} = \frac{\text{number of oxygen atoms}}{\text{molecules}} \times \text{total number of molecules}$$

$$\text{Number of oxygen atoms} = \frac{2 \text{ oxygen atoms}}{\text{molecules}} \times 6.022 \times 10^{22} \text{ molecules}$$

Number of oxygen atoms = 1.20×10^{23} oxygen atoms

$$\text{Number of carbon atoms} = 4.8 \times 10^{23} \text{ carbon atoms}$$

$$\text{Number of hydrogen atoms} = 6.022 \times 10^{23} \text{ hydrogen atoms}$$

$$\text{Number of nitrogen atoms} = 2.40 \times 10^{23} \text{ nitrogen atoms}$$

8

Mass Percent

The Mass Percent of an element is defined as:

$$\text{Mass Percent of an element} = \frac{\text{Mass of the element}}{\text{Total molar mass of the sample}} \times 100\%$$

What is the mass percent of carbon, hydrogen, and oxygen in pure ethanol $\text{C}_2\text{H}_6\text{O}$?

-First: calculate the molar mass of $\text{C}_2\text{H}_6\text{O}$

$$\begin{aligned}\text{MW of } \text{C}_2\text{H}_6\text{O} &= 2 \times \text{C} + 6 \times \text{H} + 1 \times \text{O} \\ &= 2 \times 12.01 + 6 \times 1.008 + 1 \times 16.00\end{aligned}$$

$$\text{MW } \text{C}_2\text{H}_6\text{O} = 46.07 \text{ g/mole}$$

-Second: calculate the mass percents

$$\text{Mass \% C} = 100 \times \left(\frac{\text{mass of C}}{\text{total molar mass}} \right) = 100 \times \left(\frac{2 \times 12.01}{46.07} \right) = 52.14 \%$$

$$\text{Mass \% H} = 100 \times \left(\frac{\text{mass of H}}{\text{total molar mass}} \right) = 100 \times \left(\frac{6 \times 1.008}{46.07} \right) = 13.13 \%$$

$$\text{Mass \% O} = 100 \times \left(\frac{\text{mass of O}}{\text{total molar mass}} \right) = 100 \times \left(\frac{1 \times 16.00}{46.07} \right) = 34.72 \%$$

Note that the mass percentages should add up to 100%.

$$\text{Mass \%} = \text{Mass \% C} + \text{Mass \% H} + \text{Mass \% O}$$

$$= 52.14 \% + 13.13 \% + 34.72 \% = 99.99 \%$$

9

Chemical and structural Formulas

The **chemical formula** tells you how many of each type of atom are in a molecule.

The **structural formula** tells you how many of each type of atoms are in a molecule and also how they are connected.

For example, the chemical formula for ethanol is $\text{C}_2\text{H}_6\text{O}$ and

The structural formula of ethanol is

Be careful, the chemical formula could be the same for different molecules, but the structural formula is unique.

The chemical formula for dimethyl ether is $\text{C}_2\text{H}_6\text{O}$ and

The structural formula of dimethyl ether is:

10

Empirical Formulas (simplest formula)

- It shows the simplest whole number ratio of atoms in a molecule.
- For example, hydrogen peroxide's **chemical formula** is H_2O_2 , but its **empirical formula** is HO

$$\text{Molecular Formula} = \left(\frac{\text{Molecular weight of unknown (g/mole)}}{\text{mass of Empirical formula}} \right) \times \text{Empirical formula}$$

Write the different formulas for the glucose molecule

The chemical formula for glucose is $\text{C}_6\text{H}_{12}\text{O}_6$, but its empirical formula is CH_2O , and its structural formula is

11

Combustion Analysis

- It is used to determine the mass % for different elements in the compound.

The sample is burned in the presence of excess oxygen which converts all the carbon to carbon dioxide and all the hydrogen to water.

The CO_2 and H_2O produced are absorbed in two different stages and their masses determined by measuring the increase in weight of the absorbers.

12

- **Ascorbic acid (vitamin C) contains only C, H, and O. Combustion of 1.000 g of Ascorbic acid produced 40.9% C and 4.5% H. What is the empirical formula for Ascorbic Acid?**

First: calculate the mass percent of Oxygen.

Since the sample contains C, H, and O, then the remaining 100% - 40.9% - 4.5% = 54.6% is Oxygen

Second: Suppose 100 g of this substance

Steps		C	H	O
1	Mass /g	40.9	4.5	54.6
2	No. of moles = $\frac{\text{mass}}{\text{molar mass}}$	$\frac{40.9}{12} = 3.4$	$\frac{4.5}{1} = 4.5$	$\frac{54.6}{16} = 3.4$
3	÷ smallest number (3.4)	1	1.3	1
4	x by a number to make step 3 integer numbers (x 3)	1 x 3 = 3	1.3 x 3 = 4	1 x 3 = 3
5	Empirical formula $C_3H_4O_3$	3 C	4 H	3 O

13

What is the molecular formula if the molecular mass of Ascorbic Acid was founded to be 176 g/mole?

$$\text{Molecular Formula} = \left(\frac{\text{Molecular weight of unknown (g/mole)}}{\text{mass of empirical formula}} \right) \times \text{empirical Formula}$$

$$\begin{aligned} \text{Molecular Formula} &= \left(\frac{176 \text{ (g/mole)}}{3 \times 12 + 4 \times 1 + 3 \times 16} \right) \times C_3H_4O_3 = \\ &= 2 \times C_3H_4O_3 = C_6H_8O_6 \end{aligned}$$

14

Chemical Reactions

It is process in which one or more pure substances are converted into one or more different pure substance.

All chemical reactions involve a change in substances and a change in energy.

Neither matter nor energy is created or destroyed in a chemical reaction, only changed.

Chemical equation

- When a chemical reaction occurs, it can be described by an equation.
- This shows the chemicals that react (**reactants**) on the left-hand side, and the chemicals that they produce (**products**) on the right-hand side.

Reactants Reaction conditions → **Products**

Reaction between hydrogen gas and oxygen gas to produce liquid water

hydrogen gas + oxygen gas → liquid water

15

Balancing chemical equations

- first write the correct formula for both reactants and products and then **balance** all of the atoms on the left side of the reaction with the atoms on the right side.

Write the chemical equation which represents the burning of glucose in presence of oxygen gas which produces carbon dioxide and water.

To answer this question, follow the following steps:

1. **Identify the reactants and the products and put an arrow in between.**

glucose + oxygen gas → carbon dioxide + water

2. **Try to figure out the correct formula for the reactants and products,**

Glucose is $\text{C}_6\text{H}_{12}\text{O}_6$, oxygen gas is O_2 , carbon dioxide is CO_2 , and water is H_2O .

3. **Count the number of each atom at both sides of the equation:**

16

Balance C first, then H, and finally O:

At the left side there are 6 C atoms and at the right side there are 1 C atom, so multiply CO₂ by 6 (x 6)

At the left side there are 12 H atoms and at the right side there are 2 H atom, so multiply H₂O by 6 (x 6)

At the left side there are 8 O atoms and at the right side there are 18 O atom, so multiply O₂ by 6 (x 6)

Recount all atoms again,

(6 C + 12 H + 6 O) + (12 O)
Total: (6 C + 12 H + 18 O)

(6C + 12 O) + (12H + 6 O)
(6 C + 12 H + 18 O)

17

Amount of reactants and products problems

In this type of problems, you are given the mass (#moles) of the reactant and you calculate the mass (#moles) of the product.

You can use the following formula to calculate the #moles of B:

$$\text{number of moles of (B)} = \text{number of moles of (A)} \times \left(\frac{b}{a}\right)$$

You can use the following formula to calculate the mass of B:

$$\text{mass of (B)} = \left(\frac{\text{mass of (A)}}{\text{Molar mass of (A)}}\right) \times \left(\frac{b}{a}\right) \times \text{Molar mass of (B)}$$

How many grams of water are produced when 7.00 grams of oxygen react with an excess of hydrogen according to the reaction shown below?

✓The "excess" reactant has nothing to do with the problem.

✓Identify which is the "given" and which is the unknown.

18

- Use the formula:

$$\text{mass of (H}_2\text{O)} = \left(\frac{\text{mass of O}_2}{\text{Molar mass of O}_2} \right) \times \left(\frac{2(\text{H}_2\text{O})}{1(\text{O}_2)} \right) \times \text{Molar mass of (H}_2\text{O)}$$

$$\text{mass of (H}_2\text{O)} = \left(\frac{7.0 \text{ g}}{32 \text{ g/mole}} \right) \times \left(\frac{2(\text{H}_2\text{O})}{1(\text{O}_2)} \right) \times 18 \text{ g/mole}$$

Mass of H₂O = 7.89 g

Calculate the number of moles of CO₂ resulted from the reaction of 3.5 moles of C₂H₆ with excess oxygen according to the equation

- Use the formula:

$$\text{number of moles of (CO}_2\text{)} = \text{number of moles of (C}_2\text{H}_6\text{)} \times \left(\frac{4(\text{C}_2\text{H}_6)}{2(\text{CO}_2)} \right)$$

$$\text{number of moles of (CO}_2\text{)} = 3.5 \text{ moles of (C}_2\text{H}_6\text{)} \times \left(\frac{4(\text{C}_2\text{H}_6)}{2(\text{CO}_2)} \right)$$

Number of moles of CO₂ = 7.0 moles

19

Calculate the mass of chlorine that reacts with 4.770 g of hydrogen to form hydrogen chloride according the following equation:

- Use the formula:

$$\text{mass of (Cl}_2\text{)} = \left(\frac{\text{mass of H}_2}{\text{Molar mass of H}_2} \right) \times \left(\frac{1(\text{H}_2)}{1(\text{Cl}_2)} \right) \times \text{Molar mass of (Cl}_2\text{)}$$

$$\text{mass of (Cl}_2\text{)} = \left(\frac{4.770 \text{ g of H}_2}{2.0 \text{ g/mole}} \right) \times \left(\frac{1(\text{H}_2)}{1(\text{Cl}_2)} \right) \times 71.0 \text{ g/mole}$$

Mass of Cl₂ = 169.3 g

20

Limiting Reagents

When two substances A and B are present in random quantities and react with each other to produce D, the first consumed one is *the limiting reagent* and the second one is remained in excess.

The amount of product should be calculated from the amount of the limiting reagent

To determine the limiting reagent from given moles of substance, do the followings:

- 1- Calculate the ratio for each reagent, by dividing the given moles of a reagent to its factor in the chemical equation.
- 2- Compare the ratios for the reagents and the limiting reagent is *the smallest one*.

21

If 5 moles of NO were mixed with 5 moles of O₂ to react as: $2\text{NO}(\text{g}) + \text{O}_2(\text{g}) \rightarrow 2\text{NO}_2(\text{g})$

Determine the limiting reagent.

The ratio of $\text{NO} = \frac{5 \text{ mol (given)}}{2 \text{ mol (factor)}} = 2.5$

The ratio of $\text{O}_2 = \frac{5 \text{ mol}}{1 \text{ mol}} = 5$

The limiting reactant is NO because it is the smallest

If 400g Fe were mixed with 300g O₂ to react as:

Determine the limiting reagent.

Step 1: Change the mass in grams into moles for the given substances

$$400\text{g Fe} \times \frac{1 \text{ mol Fe}}{55.8 \text{ g / mole Fe}} = 7.17 \text{ mol Fe} \quad 300\text{g O}_2 \times \frac{1 \text{ mole O}_2}{32 \text{ g / mole O}_2} = 9.38 \text{ mol O}_2$$

Step2: Calculate the ratio and compare

$$\text{Fe} = \frac{7.17 \text{ mol}}{4 \text{ mol}} = 1.793$$

$$\text{O}_2 = \frac{9.38 \text{ mol}}{3 \text{ mol}} = 3.127$$

Fe is the limiting reactant

22

Chemical Reaction Yield

- For any chemical reaction there are theoretical and actual (practical) yield.
- *Theoretical yield (T.Y.)* is the amount of product that would result if all the limiting reactant reacted.
- *Actual yield (A.Y.)* is the amount of product actually obtained from a reaction.
- Due to many factors can affected on the reaction, A.Y. is always less than T.Y.
- *Percent yield* is the efficient for a given reaction:

$$\% \text{ yield} = \frac{\text{A.Y.}}{\text{T.Y.}} \times 100$$

23

Many tons of urea ($\text{CO}(\text{NH}_2)_2$) are produced every year in fertilizer industries. When 119 g ammonia react with 80 g CO_2 as the equation: $2\text{NH}_3(\text{g}) + \text{CO}_2(\text{g}) \rightarrow \text{CO}(\text{NH}_2)_2(\text{s}) + \text{H}_2\text{O}$

and produce 100 g urea, calculate % yield?

- Step 1: Determine the limiting reagent

- Change the mass in grams into moles for the given substances

$$119\text{g NH}_3 \times \frac{1\text{mole NH}_3}{17\text{g NH}_3} = 7\text{mol NH}_3 \quad 80\text{g CO}_2 \times \frac{1\text{mole CO}_2}{44\text{g CO}_2} = 1.82\text{mol CO}_2$$

- Calculate the ratio and compare

$$\text{NH}_3 = \frac{7\text{mol}}{2\text{mol}} = 3.5 \quad \text{CO}_2 = \frac{1.82\text{mol}}{1\text{mol}} = 1.82 \quad \text{CO}_2 \text{ is the limiting reagent}$$

Now, ignore NH_3 and compare between CO_2 and $\text{CO}(\text{NH}_2)_2$ only.

- Step 2: Calculate the Theoretical Yield [#moles of $\text{CO}(\text{NH}_2)_2$]

$$\text{number of moles of (B)} = \text{number of moles of (A)} \times \left(\frac{\text{b}}{\text{a}}\right)$$

$$\# \text{ moles CO}(\text{NH}_2)_2 = \# \text{ moles of CO}_2 \times \left(\frac{1}{1}\right) = 1.82\text{moles CO}_2 \times 1$$

Number of moles of $\text{CO}(\text{NH}_2)_2 = 1.82$ moles

24

Step 3: Calculate the Theoretical Yield [mass of CO(NH₂)₂] produces:

$$\text{The T.Y.} = 1.82 \text{ mole urea} \times \frac{60 \text{ g urea}}{1 \text{ mole urea}} = 109 \text{ g urea}$$

Step 4: Calculate the %Yield of CO(NH₂)₂:

$$\% \text{ yield} = \frac{\text{A.Y.}}{\text{T.Y.}} \times 100$$

$$\% \text{ yield} = \frac{100}{109} \times 100 = 91.7 \%$$
